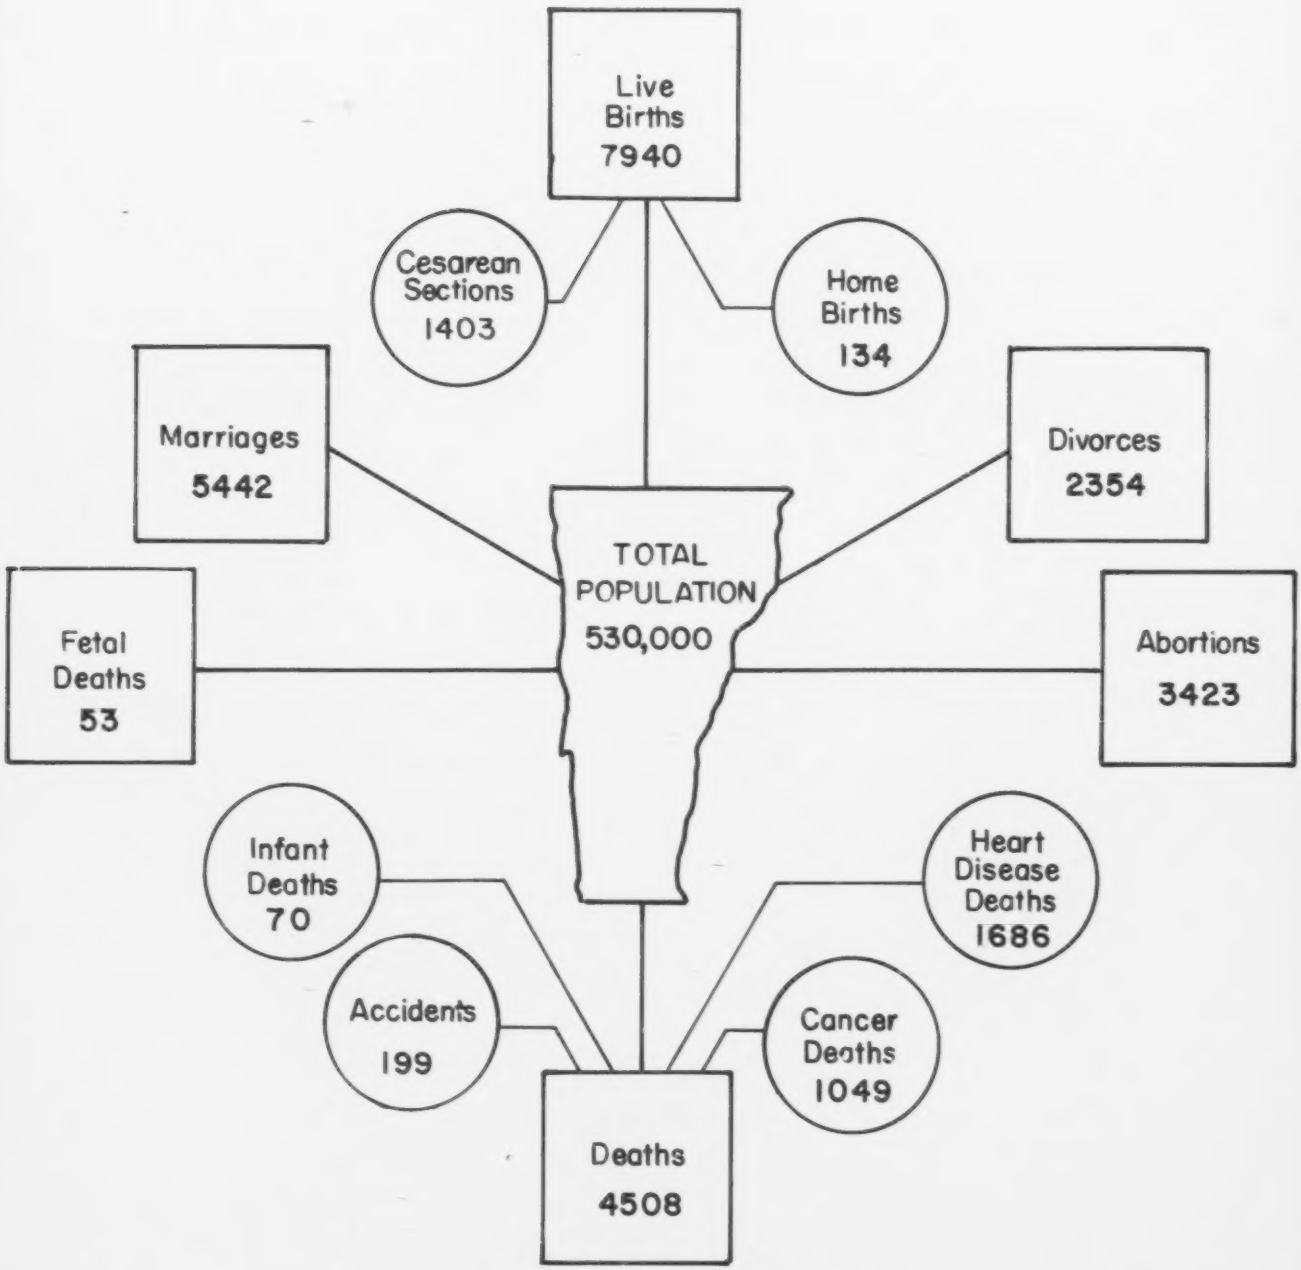
INTRODUCTION

figure 1

VERMONT VITAL EVENTS FOR 1984



Marriages, divorces, and abortions displayed above are occurrence data; all other vital events represent resident data.

The Vermont Vital Statistics System

Statewide vital registration began in Vermont in 1857, when the General Assembly passed a bill requiring that towns report all births, marriages, and deaths occurring in their jurisdiction to the Secretary of State. The legislature also required periodic publication of tables from the reports. This volume, which is the one hundredth in the series of publications begun in 1857, presents Vermont vital events for the year 1984. Historically, the information contained on vital records has served as an important tool for public health officials, by providing a picture of the general health of the population. Recognizing this importance, in 1896 the legislature transferred responsibility for the vital statistics system to the newly formed Board of Health, the forerunner of the Vermont Department of Health. The Health Department still has this responsibility.

The current Vermont vital statistics system includes six types of vital events: births, deaths, marriages, divorces, fetal deaths, and abortions. Each type of record has followed a different path before being used to produce the statistics published here.

When a birth occurs the physician, midwife, or other birth attendant is required to complete a birth certificate and file it with the town clerk in the town of birth within 10 days. For hospital births, it is usually the medical records staff who complete the birth certificate. The physician signs the completed form before it is forwarded to the town clerk.

Although the physician is also responsible for filing the death certificate, the job may be, and usually is, delegated to the funeral director. Most of the information needed to complete the death certificate is obtained from the family of the deceased. A physician, however, must complete the cause of death information and sign the death certificate. The funeral director files the certificate with the town clerk.

When a couple wishes to marry in Vermont, they provide a town clerk with the information needed to complete the marriage license. The couple takes the license to the officiant, who, after performing the marriage, signs and dates it, and returns it to the town clerk. When the town clerk files the license, it becomes the marriage certificate.

The Health Department regularly receives copies of all the births, deaths and marriages filed in local town clerks' offices.

A divorce certificate is initiated by the lawyer or other individual handling the divorce. It is filed with the court as part of the divorce proceedings. The court keeps the certificate until the divorce decree becomes final, usually three months after the court hearing. When the decree is final, the court clerk signs the certificate and sends it to the Health Department for filing.

Reports of fetal death and induced termination of pregnancy are filled out by the physician attending the mother. They are sent directly to the Health Department. These reports are not legal records, and are for statistical use only. After the data are extracted from them, these reports are destroyed.

All vital records received at the Health Department are computerized. Records are coded and entered into the computer. Records with unknown or unlikely data are corrected after querying the data provider. A computer tape containing statistical information from the records is sent to the National Center for Health Statistics to become part of the national data base.

Because most analysis of vital events is based on Vermont resident, rather than occurrence, data, the Health Department receives copies of certificates of all Vermont resident births and deaths that occur in other states in the United States and Canada.

Vital statistics data are used for reports like this one, for aiding in population estimates, for targeting areas of public health concern, and for special studies. Recent special studies the Health Department has conducted include infant deaths, suicide, cancer mortality, and teenaged pregnancy. The 100 volumes of Vermont's vital statistics illustrate the changes in Vermonters' health status and needs over time.

The tables presented in this bulletin were derived from vital events filed at the Health Department for calendar year 1984. All rates are based on estimates of the Vermont midyear 1984 population (Table 2) developed by the Division of Public Health Statistics.

Eight new tables have been added to this publication. They are:

Births - hospital of delivery by type of delivery.
Abortion - weeks of gestation by age of patient, weeks of gestation by type of facility, and type of facility by abortion procedure.
Pregnancy tables - (combining births, fetal deaths and abortions) showing age of woman by county of residence; age specific pregnancy rates by age and county of residence; age of woman by education; and age of woman by marital status.

The following section, "How to Be a Vital Statistician", is also new. It describes the basic steps one should take when using the tables presented in this book.

Finally, Appendix B outlines data accuracy problems found in some of the birth items. Researchers using the birth tables in this book are encouraged to read this section.

HOW TO BE A VITAL STATISTICIAN *

This book presents vital statistics and highlights a number of important demographic and public health changes. The possible uses of vital statistics are endless. Data users are as diverse as a public health official evaluating a program and using death data, a demographer projecting school enrollments with birth data, and a business person deciding to open a formal wear shop based on marriage data. Many of these users have a thorough knowledge of statistics. Others find the entire subject matter confusing and intimidating. For either group a misunderstanding of what vital statistics mean or an incorrectly used comparison can lead to wrong conclusions. Therefore, this section is included to provide an overview of how to use vital statistics. It is addressed to the person looking at vital events for the first time, but the experienced user may also find a review helpful. Additional information about specific events is provided at the beginning of each section.

STEP 1: FINDING THE CORRECT NUMBER

The first step is to determine how many of a particular vital event took place during the year. This involves asking two questions:

Which event or events are appropriate?

DEATHS
INFANT DEATHS
NEONATAL DEATHS
POST-NEONATAL DEATHS
FETAL DEATHS
LOW BIRTH WEIGHT INFANTS
PREGNANCIES
INDUCED ABORTIONS
MARRIAGES
DIVORCES

This may not be as simple as it sounds. For one thing, examining more than one type of event may be required. For example, a researcher who is concerned with teenaged pregnancies will have to consider abortions and fetal deaths, not simply the number of births.

---

* This Appendix is reprinted with the permission of the Oregon Center for Health Statistics from their "OREGON VITAL STATISTICS, 1983" publication. Examples have been changed to Vermont examples.

Deciding which events to use is important since sometimes the choice of one event over another can lead to vastly different conclusions. Consider the researcher who asks, "Have we reduced the problem of teenaged fertility in Vermont?" Examining teenaged births suggests the answer is yes. Examining teenaged pregnancies suggests not.

What is the correct population?

Vital events do not usually occur in individuals' homes, which leads to an interesting problem in geography. Vital events are usually reported two ways:

OCCURRENCE - means that the event (death, birth, marriage) actually took place in the geographic region indicated (either Vermont or a particular county). The person participating in the event may have lived in Timbuktu.

RESIDENCE - means that the person involved in the event lived in the geographic region mentioned, but the event itself may have taken place anywhere in the United States or Canada. In other words, a resident of Windham county who died in an accident while on vacation in Michigan is included in the Windham county resident death figure.

Choosing the appropriate population is important. Occurrence birth data is more relevant to a hospital planner who is deciding whether to expand or contract delivery services. But residence birth data should be the choice for projecting school enrollment. When in doubt about which population to use, resident figures are usually the better choice. Most birth and death data are published by residence, which means that comparisons with other states or the United States as a whole are easier. In this book, table headings indicate the population included in the tables.

Once the right event and the right population have been determined, the statistician can find the correct figures in the table(s) in this book. If the needed table is not listed, contact the Division of Public Health Statistics at the Vermont Department of Health for more information.

STEP 2: MAKING THE NUMBER MEANINGFUL WITH RATES AND RATIOS

In many instances simply knowing the number of events which occurred is not sufficient. A. Bradford Hill expressed this important statistical concept:

> "It is well recognized that white sheep eat more than black sheep -- because there are more of them."

In other words, it is the probability of the event which is important. We know more people died in Chittenden county than in Franklin county, but is the likelihood of dying really different?

In order to answer this question, statisticians calculate rates. This means that the number of events which occurred is compared to the population for which that event could have occurred, and the figure is then standardized to some number (such as 1,000 or 100,000) for convenience.

Here is an example:

$$\text{CRUDE DEATH RATE} = \frac{\text{DEATHS}}{\text{POPULATION}} \times 1{,}000$$

DEATHS: the number of people who could have died

POPULATION: the number of people who could have died

1,000: a number picked by vital statisticians to eliminate decimal points.

The more specifically a statistician can define the "population at risk" (the bottom part of the rate), the more meaningful the rate is. For example, the crude birth rate, which compares the number of births to the population, is not nearly as informative as the fertility rate. This second rate uses only the number of women of childbearing age (15-44) for comparative purposes and is therefore less distorted by quirks in the population distribution. (The turn of the century notion that only married women between the age of 15 and 44 would be considered at risk of pregnancy has been abandoned for obvious reasons.) The importance of being specific about the population at risk is explained in Step 3.

Unfortunately, we do not always have the correct number for the bottom part of the equation. In these situations a substitute is used. For example, how many people are at risk of getting divorced? The number of married people is only available for census years. As a substitute, the crude divorce rate is calculated using the total population regardless of marital status. In other situations, the event is simply compared to another related number to create a ratio. For instance, the abortion ratio compares the number of abortions to the number of births. This is easier and more accurate than trying to

determine the true denominator, which is the total number of pregnant women.

When calculating rates and ratios, great care must be taken to make certain that the same time periods, the same geographical boundaries, and the same population are used in the top and bottom parts of the equation.

STEP 3: COMPARING PLACES, TIME PERIODS, AND CATEGORIES

In many situations, the vital statisticians's goal is to compare two or more numbers for different geographical areas, different time periods, or different categories such as men versus women. But comparing rates and ratios introduces some new problems which must not be overlooked.

Changes in measurement

The first problem is that the measures being compared are not always the same. Definitions, population estimates, certificates, and coding procedures change from time to time as the need arises. This can create "artificial" differences and can disguise "real" differences. The cause of death item provides an excellent example of changes in comparability:

> Between 1975 and 1978 approximately 50 people died each year from chronic obstructive pulmonary disease.
> RATE= 9.6 PER 100,000 POPULATION.
>
> Between 1979 and 1983, approximately 160 people died each year from this cause.
> RATE = 31.7 PER 100,000 POPULATION

The explanation for the difference since 1979 is not that the incidence of C.O.P.D. deaths increased, but that a new scheme for coding causes of death was introduced that year.

Taking age and sex into account

Mr. G. C. Wipple noted in 1923 that, "We might find that the death rate of bank presidents was higher than that of newsboys; but this would not be because of different occupations, but because of different ages." We expect older people to die at a higher rate than younger people. We also expect people in their twenties to have more babies than the very young or the very old. Sex and race, as well as age, affect rates drastically.

When comparing two places or two points in time, it is necessary to take these influencing characteristics into account. Here is an example:

> In 1984, 28 people from Chittenden county and 27 people from Rutland county died of accidental causes. Because Chittenden county has many more people (121,360 compared to 59,807), the accidental death rate for Chittenden county is much lower than Rutland's: 23.1 compared to 45.7 per 100,000 population.

In this book, Vermont rates are compared to United States white rates, rather thant to total United States rates because Vermont's population is predominantly white (99.1 percent).

Before comparing two places or two time periods, always compare the population characteristics first. If discrepancies are noted in any relevant variables, then the rates should be adjusted or standardized in order to make the comparisons free of differences in the structure of the populations. The formulas for doing this are listed at the end of this section.

Small Numbers

Perhaps the most common error made in vital statistics concerns the use of rates based on very small numbers. When the numbers being used to calculate rates are extremely small, large swings often occur in the rates which do not reflect real changes. Consider Franklin county's infant mortality rates for the past five years:

FRANKLIN COUNTY

YEAR	BIRTHS	INFANT DEATHS	INFANT DEATH RATE
1980	644	7	10.9
1981	555	4	7.2
1982	649	5	7.7
1983	605	4	6.6
1984	625	6	9.6
TOTAL	3,078	26	8.4

The overall rate of 8.4 is quite close to the state rate

of 9.1 for the same time period. Yet the rate varies widely with the addition or subtraction of just one death. Public health officials would waste a good deal of energy if they reacted to these annual rates.

Statisticians expect a certain amount of chance variation and have methods to take this into account. The confidence interval uses the number of cases and their distributions to determine what the rate "really is". For example, a statistician will say, "We are 95 percent sure that the true infant death rate for Vermont between 1980 and 1984 was 9.1 plus or minus .73, that is, it lies somewhere between 8.37 and 9.83." If two rates have overlapping confidence intervals, than the difference between them may be due to this chance variation. In other words, the difference between them is not statistically significant.

Franklin county's infant death rate for the same period was 8.4 plus or minus 3.2. The difference between the state rate and Franklin county's rate is not statistically significant.

When comparing rates and ratios, differences should be tested for statistical significance. Formulas are at the end of this section. For those who are reluctant to use formulas, consider this rule of thumb: a rate based on 20 cases has a 95 percent confidence interval about as wide as itself (the interval for a rate of 50 is between 25 and 75). Even large differences between two rates based on 20 cases or less are probably not statistically significant.

If 20 are too few, how many cases are sufficient to say that a true difference exists? Unfortunately, we have no easy rule for this. To be safe, the vital statistician should always try to combine several years of data or consolidate geographical areas.

Many rates based on small numbers are published in this book because readers demand them. Anyone preparing to make important decisions based on these rates should make an effort to determine if the rates are statistically significant.

STEP 4: ANALYZING THE DATA

The first three steps are fairly mechanical:

1. Choose the correct events and the correct population to determine the number of events which took place for the geographical areas and time periods.

2. Calculate the rates.

3. Compare these rates to determine if the differences are statistically significant.

Now the vital statistician must begin to ask the difficult questions. Just because two rates are different, can we assume that we have a case of cause and effect? Is there another factor which is really causing the changes in the rates? If the difference which we expected did not prove to be significant, is there another item which perhaps is masking the difference? Frequently the statistician has to refine the research question and begin all over again.

Several sources of help are available. Many of the widely used rates and ratios are presented in the Summary Statistics section, and narratives and figures are included throughout the book to illustrate changes. And finally, the staff of the Division of Public Health Statistics are available for data users who need assistance.

Basic Definitions

The following definitions apply throughout this report:

A LIVE BIRTH is the complete expulsion or extraction from its mother of product of conception, irrespective of the duration of pregnancy, which after such separation, breathes or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

A DEATH is the permanent disappearance of any evidence of life at any time after live birth.

A MARRIAGE is the legal union of persons of opposite sex.

A DIVORCE is the final legal dissolution of a marriage.

An ANNULMENT is the invalidation or voiding of a marriage which confers on the parties the status of never having been married to each other.

A reportable FETAL DEATH is a death prior to the complete expulsion or extraction from its mother of a product of conception, having passed through at least the 20th week of gestation or weighing more than 400 grams; the fetus shows no signs of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

An ABORTION is the purposeful interruption of pregnancy with the intention other than to produce a live-born infant or to remove a dead fetus.

A NEONATAL DEATH is a death occurring in the first 28 days of life.

An INFANT DEATH is a death occurring in the first year of life.

A PERINATAL DEATH is a fetal death or a death occurring in the first week of life.

A MATERNAL DEATH is the death of a woman from causes related to pregnancy.

WEEKS OF GESTATION is the number of weeks elapsed between the first day of the last menstrual period and the date of delivery.

PLURALITY is the number of siblings born as a result of this pregnancy.

RESIDENCE Usual place of residence for person to whom event occurred. For births and fetal deaths residence is defined as the mother's usual place of residence.

OCCURRENCE Place where the event actually occurred.

RATES

Crude Birth Rate	$= \frac{\text{No. of resident live births}}{\text{Total resident population (mid-year)}} \times 1000$
Fertility Rate	$= \frac{\text{No. of resident live births}}{\text{Total resident female population (15-44)}} \times 1000$
Age-specific Fertility Rate	$= \frac{\text{No. of resident live births to mothers in a specific age group}}{\text{Total female population in specific age group (mid-year)}} \times 1000$
Pregnancy Rate	$= \frac{\text{No. of resident pregnancies}}{\text{Total resident female population (15-44)}} \times 1000$
Age-Specific Pregnancy Rate	$= \frac{\text{No. of resident pregnancies to mothers in a specific age group}}{\text{Total female population in specific age group (mid-year)}} \times 1000$
Crude Death Rate	$= \frac{\text{No. of resident deaths}}{\text{Total resident population (mid-year)}} \times 1000$
Age-specific Death Rate	$= \frac{\text{No. of deaths in specific age group}}{\text{Total resident population in specific age group}} \times 1000$
Marriage Rate	$= \frac{\text{No. of marriages}}{\text{Total resident population (mid-year)}} \times 1000$
Divorce Rate	$= \frac{\text{No. of divorces and annulments}}{\text{Total resident population (mid-year)}} \times 1000$
Infant Death Rate	$= \frac{\text{No. of resident infant deaths}}{\text{Total resident live births}} \times 1000$
Neonatal Death Rate	$= \frac{\text{No. of resident neonatal deaths}}{\text{Total resident live births}} \times 1000$
Fetal Death Rate	$= \frac{\text{No. of resident fetal deaths}}{\text{Total resident live births and resident fetal deaths}} \times 1000$
Perinatal Death Rate	$= \frac{\text{No. of resident perinatal deaths}}{\text{Total resident live births and resident fetal deaths}} \times 1000$
Abortion Ratio	$= \frac{\text{No. of resident abortions}}{\text{Total resident live births}} \times 1000$

Age adjusted rates:

Age adjusting allows one to compare rates among populations having different age distributions by adjusting the crude rates in each population to a standard population base. (In this bulletin, county rates are adjusted to the state population distribution). The computation formula is:

$$\text{The sum of } \frac{\text{Age specific rate for each age group} \times \text{Standard population in that age group}}{\text{Total standard population}} \times 1000$$

$$\text{Confidence Interval - at the 95 percent level} \quad \text{Rate per 1000} \pm 1.96 \sqrt{\frac{\text{Rate} \times (1000-\text{Rate})}{\text{Population}}}$$

CONFIDENCE INTERVALS CALCULATED FOR VARIOUS RATES AND POPULATION SIZES

Rate per 1000 Population

Population Size	5	10	20	40	100	200	500
25	28	39	55	77	118	157	196
50	20	28	39	54	83	111	139
100	14	19	27	38	59	78	98

Statistical Significance:

$$\text{Compute} \pm \sqrt{(\text{First confidence interval})^2 + (\text{Second confidence interval})^2}$$

If the interval obtained from this calculation does not include 0, then the difference is statistically significant at the 95 percent level.

SUMMARY STATISTICS

SUMMARY OF 1984 VITAL EVENTS

	Occurrence Number	Residence	
		Number	Rate
Births	7805	7940	15.0/1000 Population
Deaths	4637	4508	8.5/1000 Population
Natural Increase		3432	6.5/1000 Population
Infant Deaths		70	8.8/1000 Population
Fetal Deaths		53	6.3/1000 Population
Abortions	3423	2439*	
Marriages	5442		10.3/1000 Population**
Divorces	2354		4.4/1000 Population**

Estimated Mid-year population: 530,000

*Does not include out of state occurrences
**Based on number of occurrences

SUMMARY STATISTICS

In 1984, 23,732 vital events were registered in Vermont. Another 1,147 records from other states were added to the registered events to complete our resident statistics.

The 7,940 resident births represent a crude birth rate of 15.0 births per 1,000 population. This rate has been declining since 1979, and should continue to decline as our population ages.

The 4,508 deaths represent the lowest number of deaths recorded since 1979. The crude death rate of 8.5 deaths per 1,000 population is consistent with the rates of this decade. The four leading causes of death are heart disease with 318.1 deaths per 1,000 population, malignant neoplasms (cancer) with 197.9, cerebrovascular disease with 54.2 and accidents with 37.3. These four causes have maintained this ranking for the past 30 years.

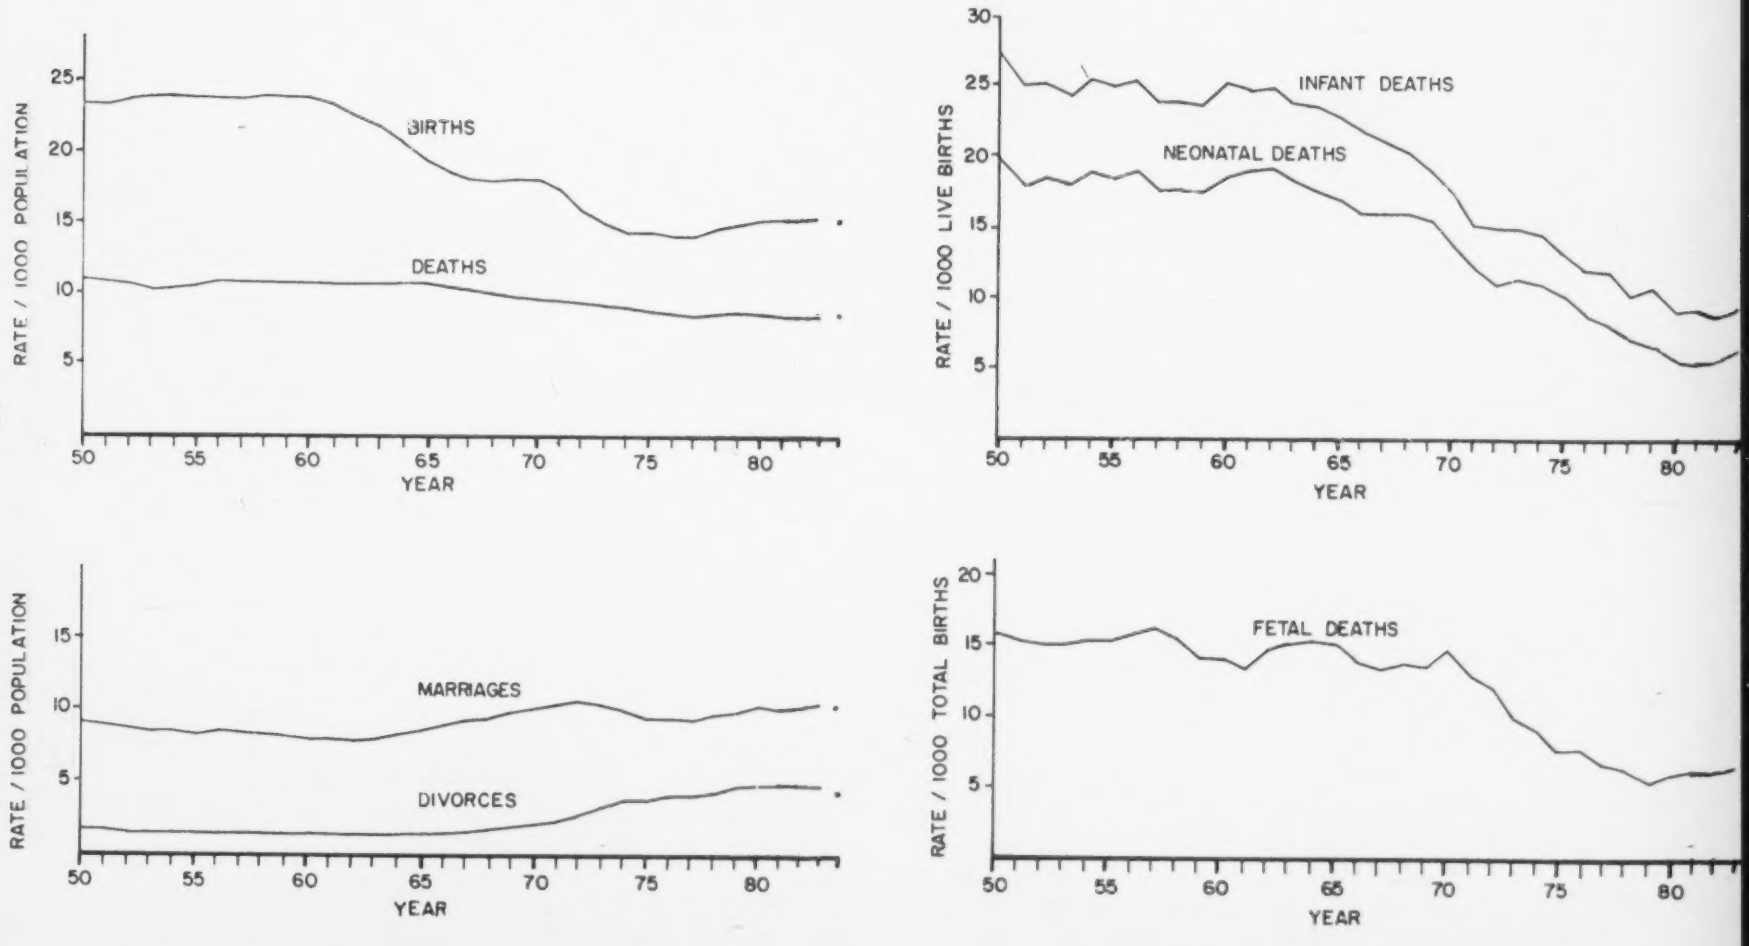
The infant death rate of 8.8 infant deaths per 1,000 live births has remained fairly constant over the past several years. The number of fetal deaths increased from 1983 to 1984. The 1984 rate of 6.3 fetal deaths per 1,000 live births and fetal deaths is consistent with years prior to 1983. The 1983 rate was unexpectedly low, perhaps due to an underreporting of fetal deaths in that year. The abortion ratio (abortions/1,000 live births) of 307.1 is similar to the 1983 ratio of 306.1. Both years represent a decline from the earlier years of the decade when the ratio was approximately 322. This number should be used with caution, since it does not include abortions to Vermont women which occurred outside of Vermont.

There were 5,442 marriages performed in 1984, 10.3 for every 1,000 Vermonters. There were 2,354 divorces granted, 4.4 per 1,000 Vermonters. The marriage rate has remained fairly stable during the 1980's. The divorce rate has dropped somewhat, as has the national divorce rate.

Figure 2

SELECTED VITAL EVENT RATES, VERMONT, 1950 - 1984

THREE YEAR MOVING AVERAGES*



* THE MOVING AVERAGE FOR A GIVEN YEAR IS THE AVERAGE OF THE DATA FOR THAT YEAR AND THE 2 ADJACENT YEARS. NO AVERAGE IS CALCULATED FOR END YEARS. THIS TECHNIQUE ATTENUATES RANDOM VARIATION.

[1]Population is the census population for those years when the census was taken and is mid-year estimates for non-census years.

[2]Rate per 1000 population.

[3]Rate per 1000 women aged 15-44.

[4]Number of pregnancies includes Live Births and Fetal Deaths for 1857-1972, and Live Births, Fetal Deaths and Abortions for 1973-present.

[5]Rate per 1000 live births.

[6]Rate per 100 live births and fetal deaths.

*Data for these years is based on occurrence returns only.

**1857 population is the 1860 census population.

#1857 was the first year that town clerks were required to report vital events to the Secretary of State and returns for that year are incomplete.

&Population figures and rates for these years have been changed from older publications of this table to correspond to the census figures and revised mid-year estimates.

##Reporting requirements were changed and includes only those of 20 or more weeks gestation or weighing 400 or more grams.

BIRTHS *

In 1984, 7,940 Vermont women had babies, 10 fewer than in 1983. The birth rate, or number of births per 1,000 Vermont residents, was 15.0, the lowest rate since 1978. The fertility rate of 60.9 births per 1,000 women aged 15 to 44, continues the slow decline of recent years.

The tables in this section cover three major topics: first, the demographic characteristics of the mothers and babies (eg., where they live, the age and education of the mother, and the sex and race of the child); second, the health care the mother received during her pregnancy, measured by the month prenatal care began and the number of prenatal visits; and finally, the birth outcome and the health of the baby. Weeks of gestation, birth weight, and hospital and attendant at birth are examples of these tables. A new table, hospital by method of delivery (table 24), has been added to this section.

In 1984, Franklin and Grand Isle counties had the highest fertility rates (76.1 and 77.3 respectively), while Chittenden and Essex counties had the lowest (53.8 and 53.0). Women aged 25 to 29 were the most likely to give birth - 10.4 percent of them had babies; 9.9 percent of women aged 20 to 24 and 7.1 percent of women aged 30 to 34 also had babies.

The number of teenaged mothers continued to decline in 1984. Teenaged women had 801 babies, which represents 1 birth for every 30 Vermont women aged 15 to 19. In 1974, one in 24 women aged 15 to 19 had babies, while in 1960 the number was 1 in 14. However, the percent of births to unmarried teenagers has risen from 10 percent in 1960 to 55 percent in 1984.

---

* In 1984 the Vermont Department of Health conducted a study to determine how accurately the data recorded on birth certificates reflect the actual pregnancy and birth events. Results showed that while the majority of data are accurate, some data items - specifically, weeks of gestation, number of prenatal visits and month prenatal care began - should be used with caution. Appendix B provides detailed information about these items and their limitations. The Health Department and the hospitals have modified their data collection procedures as a result of the study, in order to continue to improve the quality of the data and, therefore, its usefulness.

Overall, 16 percent of the 1984 Vermont mothers were not married. This number has been steadily increasing. Twenty-five years ago, only three percent of mothers were unmarried, and ten years ago, nine percent were unmarried.

The trend toward smaller family size which began in the 1970's continued in 1984. In 1984 almost half (43 percent) of the mothers were having their first child, and only one-fifth (21 percent) of the births were to women who had already had at least two children. Twenty-five years ago only a quarter (26 percent) of mothers were having their first child, while more than half (52 percent) had already had two children. See figure 4.

The month of pregnancy when prenatal care began is one indicator of the adequacy of a woman's prenatal care. In 1984, 82 percent of the women giving birth began their care in the first trimester of pregnancy. Ten years ago, only 66 percent of the mothers started their care in the first trimester. One of the Health Department's objectives for the decade is that by 1990, 95 percent of mothers will begin their care in the first trimester. Teenaged mothers are not as likely to start their care early in pregnancy. In 1984, only 60 percent of these mothers received prenatal care in the first trimester.

Prematurity is a major cause of infant mortality, as well as growth and developmental problems. Low birth weight, one measure of prematurity, is defined as a newborn weighing under 2500 grams (5 1/2 pounds). In 1984, 6.1 percent of Vermont births were low birth weight babies, a number which has been quite stable for the past 5 years. It compares to 6.8 percent ten years ago, and 6.9 twenty-five years ago. Teenagers are much more likely to have a low birth weight baby than older mothers. In 1984, 9.5 percent of the babies born to teens weighed under 2500 grams.

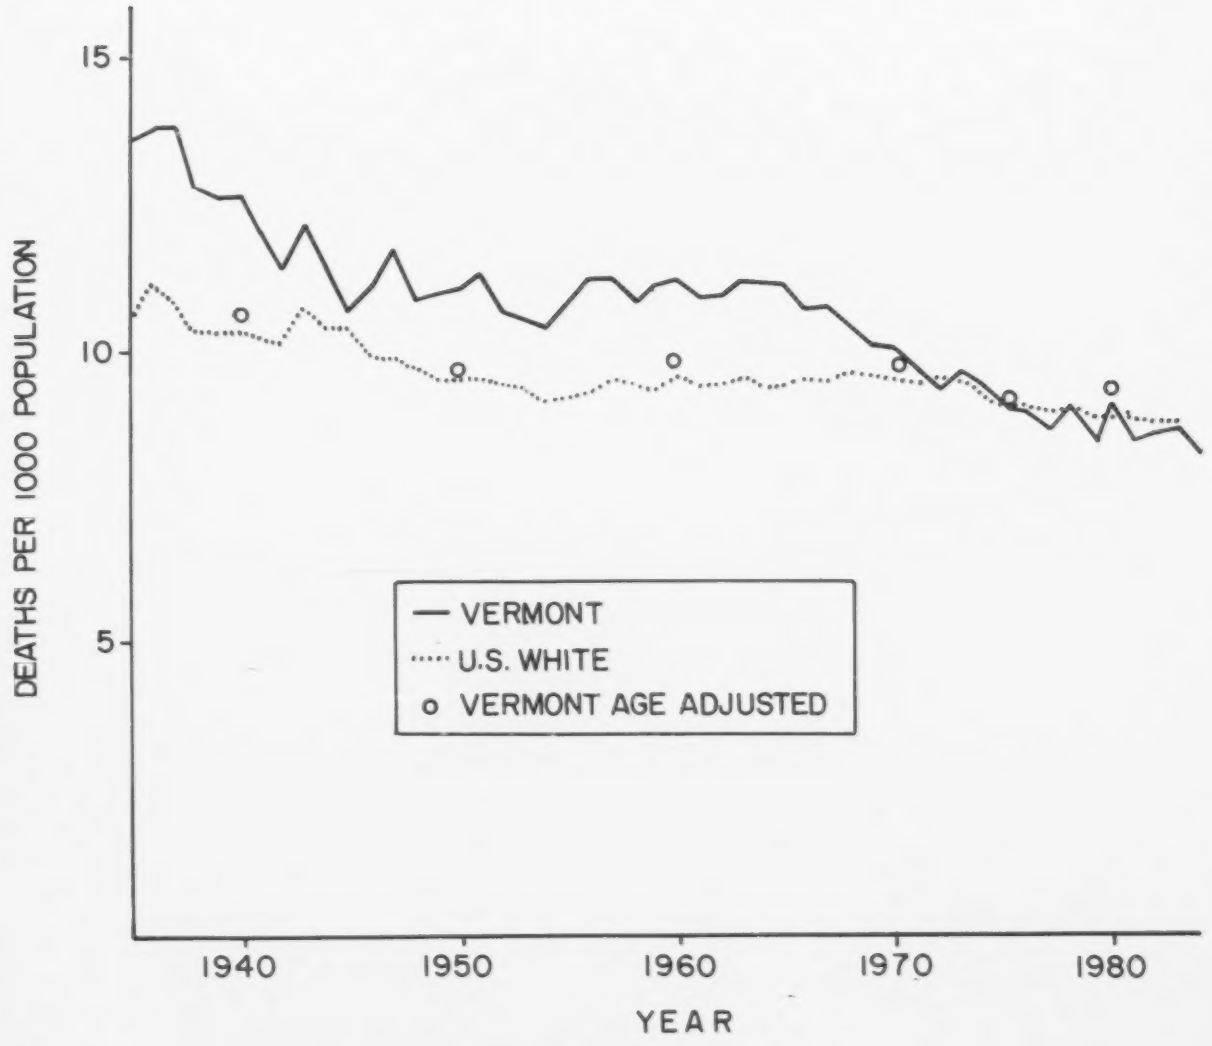
DEATHS

Figure 6

VERMONT AND U.S. WHITE CRUDE DEATH RATES, 1935-1984



U.S. RATE FOR 1984 IS PROVISIONAL

DEATHS

In 1984, 4,508 Vermont residents died. This represents 8.5 deaths for every 1,000 Vermonters. This crude death rate has remained fairly constant throughout the 1980s and compares to the 1983 provisional United States white rate of 8.8 per 1,000.

Seventy percent of the deaths were due to four major causes, heart disease (37 percent), cancer (23 percent), cerebrovascular disease (6 percent) and accidents (4 percent). Deaths due to heart disease, cerebrovascular accidents, and accidents have decreased since 1980. Cancer deaths, however, have continued their slow increase. (see table 25).

Some diseases are mentioned much more frequently on a death certificate than is apparent by an examination of underlying causes of death only. For example, 79 people (1.8 percent) died of diabetes mellitus, but 342 death certificates (7.6 percent) mentioned diabetes; hypertension, responsible for 13 deaths (0.3 percent), was mentioned on 224 certificates (5.0 percent); and pneumonia was the underlying cause in 167 deaths (3.7 percent), but mentioned on 493 certificates (10.7 percent). (See table 40).

Leading causes of death differ among age groups, with younger deaths more likely to be accident related. Cancer is the leading cause of disease-related deaths among Vermonters aged 5 to 55. In 1984 the leading cause of death for 5-14 year olds was cancer, rather than accidents. This is a result of a decrease in accident mortality, not an increase in cancer mortality. Due to the small number of deaths in this age category (12), the decline in accidental deaths may be simply random fluctuation.

The age at which people die has changed remarkably in this century. In 1900, nineteen percent of all deaths were to infants under one. in 1984, only 1.5 percent of decedents were infants. In 1984, 74 percent of the deaths were to people over 65, compared to 37 percent in 1900. (see figure 8).

Males continue to die at earlier ages than females. This is reflected in the most recent Health Department life expectancy estimates, which show life expectancy at birth to be 74.9 years; 71.1 years for male babies, and 78.7 for females. The complete life table publication is available upon request.

Some causes of death reflect a gender bias. Males are the more likely victims of death due to suicide (77 percent), homocide (73 percent), accidents (71 percent) and lung cancer (70 percent), while females are more likely to die from cerebrovascular disease (66 percent), hypertensive heart disease (62 percent) and ulcer related conditions (61 percent).

*Cause of death is coded by the International Classification of Diseases, Adapted (ICDA). Deaths in 1952-57 were coded according to the 6th ICDA revision (ICDA-6), 1958-67 deaths according to ICDA-7, 1968-78 deaths according to ICDA-8 and ICD-9 are given in addition to comparability ratios which have been applied to earlier rates to make them comparable to the 1979-82 rates. (Ratios from "Monthly Vital Statistics Report", Volume 17, #8 Supplement, October 25, 1968, and Volume 28, #11 Supplement, February 29, 1980; DHEW, NCHS, Washington, D.C.).

PLACE CODES:

HOME: INCLUDING HOME PREMISES AND ANY NON-INSTITUTIONAL PLACE OF RESIDENCE AND EXCLUDING TEMPORARY RECREATIONAL SHELTERS , SUCH AS TRAVEL TRAILERS, TENTS, AND HUNTING CABINS.
FARM: INCLUDING BUILDINGS AND LAND UNDER CULTIVATION BUT EXCLUDING THE FARM HOUSE.
MINE AND QUARRY: INCLUDING GRAVEL, SAND PITS, AND ABANDONED MINES.
INDUSTRIAL: INCLUDING MANUFACTURING, CONSTRUCTION AND OTHER PLACES OF AN INDUSTRIAL NATURE.
RECREATIONAL: INCLUDING ALL PLACES OF RECREATION.
STREET, HIGHWAY, AND SIDEWALKS: EXCLUDING ACCIDENTS ON HOME PREMISES SIDEWALKS.
PUBLIC BUILDINGS: INCLUDING INJURY TO PEOPLE OTHER THAN THOSE INVOLVED IN CONSTRUCTION WORK.
FIELD, FOREST: EXCLUDING PART OF FARM OR RECREATIONAL SITE.
LAKE, RIVER OR STREAM: WHEN NOT A RECREATIONAL SITE.

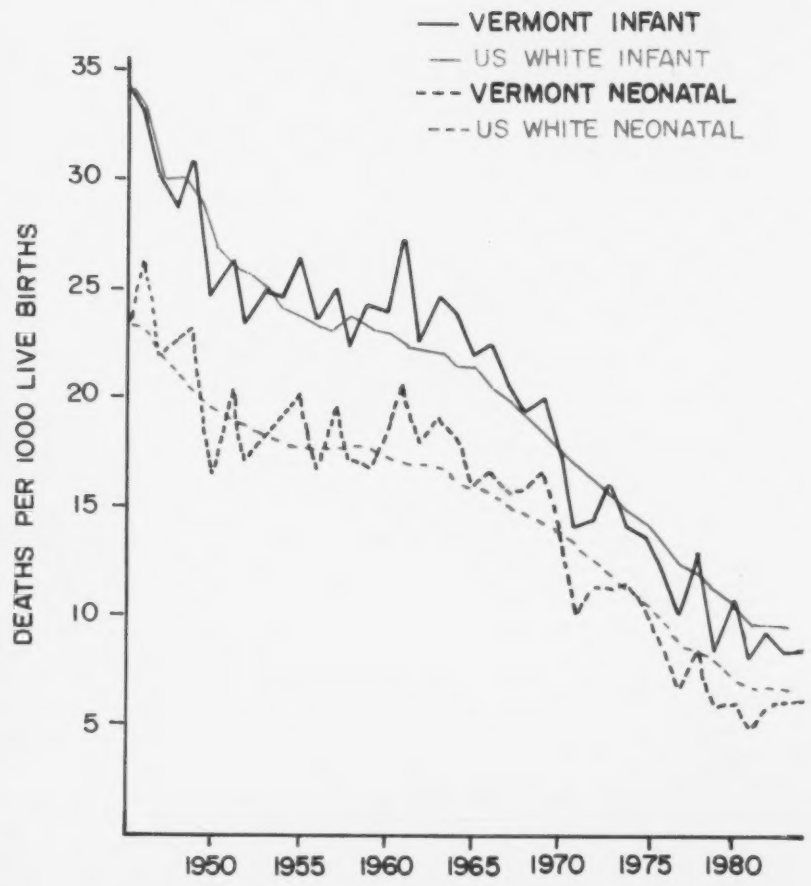
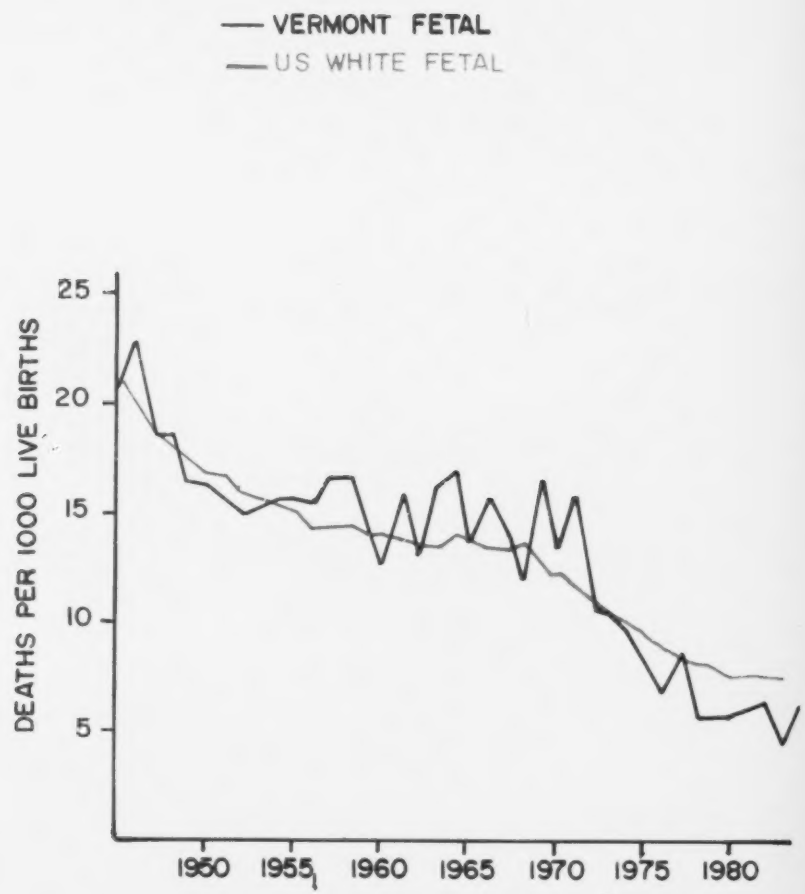
INFANT DEATHS
FETAL DEATHS
ABORTIONS AND
PREGNANCIES

Figure 9

VERMONT AND U.S. WHITE INFANT AND NEONATAL MORTALITY RATES AND FETAL MORTALITY RATIOS 1945-1984





U.S. DATA FOR 1984 WERE UNAVAILABLE AT TIME OF PUBLICATION.

INFANT DEATHS, FETAL DEATHS, ABORTIONS AND PREGNANCIES

The 1984 infant mortality rate was 8.8 deaths per 1,000 live births. The infant mortality rate has remained fairly constant over the past five years, and remains lower than the 1983 United States white rate of 9.7. The major causes of infant deaths in 1984 were conditions originating in the perinatal period (27 deaths), congenital anomalies (20 deaths), and Sudden Infant Death Syndrome (13 deaths). Most infant deaths occurred shortly after birth; 28 (40 percent) died in the first day, 39 (56 percent) died in the first weeks, and 55 (79 percent) died in the first two months.

The fetal death and abortion statistics in this section are derived from records that occurred in Vermont only. The Health Department does not receive information about fetal deaths and abortions that occur to Vermont women in other states.

There were 53 Vermont resident fetal deaths in 1984, yielding a rate of 6.6 fetal deaths per 1,000 live births and fetal deaths. This is substantially higher than last year's rate of 4.6. This difference may be attributable to an underreporting of fetal deaths in 1983. In 1984, the Health Department notified all hospitals and obstetricians of the need for proper and complete reporting of fetal deaths. The 1984 rate is comparable to the 1981 and 1982 rates of 6.2 and 6.7 respectively.

There were 3,423 abortions performed in Vermont in 1984, 68 more than 1983, and 75 less than 1982. The number of abortions performed on Vermont women (2,439) compares to 2,433 in 1983. The 1984 abortion ratio was 30.7 abortions per 100 live births. As in previous years, women terminating their pregnancies tend to be single (71 percent), and young (65 percent were under 25).

The pregnancy tables given here are new tables added this year. They have been produced by combining the birth, fetal death and abortion data. Because we do not have data on fetal deaths and abortions to Vermont women which occurred outside of Vermont, these data represent an underreporting of pregnancies. The tables include all Vermont resident births, and all Vermont resident fetal deaths and abortions which occurred in Vermont. It is hoped that despite these large limitations, the data may prove useful. The tables include pregnancy rates by age and county of residence, as well as numbers of pregnancies by age and county of residence, mother's education, and marital status. The

percent of births and induced abortions is given for each cell. The percent due to fetal deaths has been omitted because of their small numbers.

The county with the highest pregnancy rate in 1984 was Lamoille, where 99.1 of every 1,000 women aged 15-44 was pregnant. The lowest rate of 59.9 was recorded in Essex county. Vermont women in their twenties had the highest rates of pregnancy. One in eight Vermont women in their twenties was pregnant in 1984.

Orleans county women who became pregnant were most likely to complete their pregnancy with live birth (87 percent). Pregnant women in Lamoille county were least likely to complete the pregnancy (67.3 percent).

Over half of the teenaged pregnancies were terminated (51.5 percent), while only 15.7 percent of women aged 30-35 terminated their pregnancies.

Women with a high school education who became pregnant in their twenties were more likely to have a live birth than women with a college degree (78 and 43 percent respectively). The opposite is true for women in their thirties, where only 60 percent of the high school graduates, and 86 percent of the college graduates had live births.

Pregnancies to married women usually result in live births. The younger the woman, the more likely this is: 98 percent of pregnancies to married women under 18 resulted in a live birth whereas 84 percent of pregnancies to married women over 40 ended in live birth. In all age groups, unmarried women are more likely to terminate their pregnancy than have a live birth. Unmarried women aged 30 to 34 had the highest percent of terminations, 67 percent.

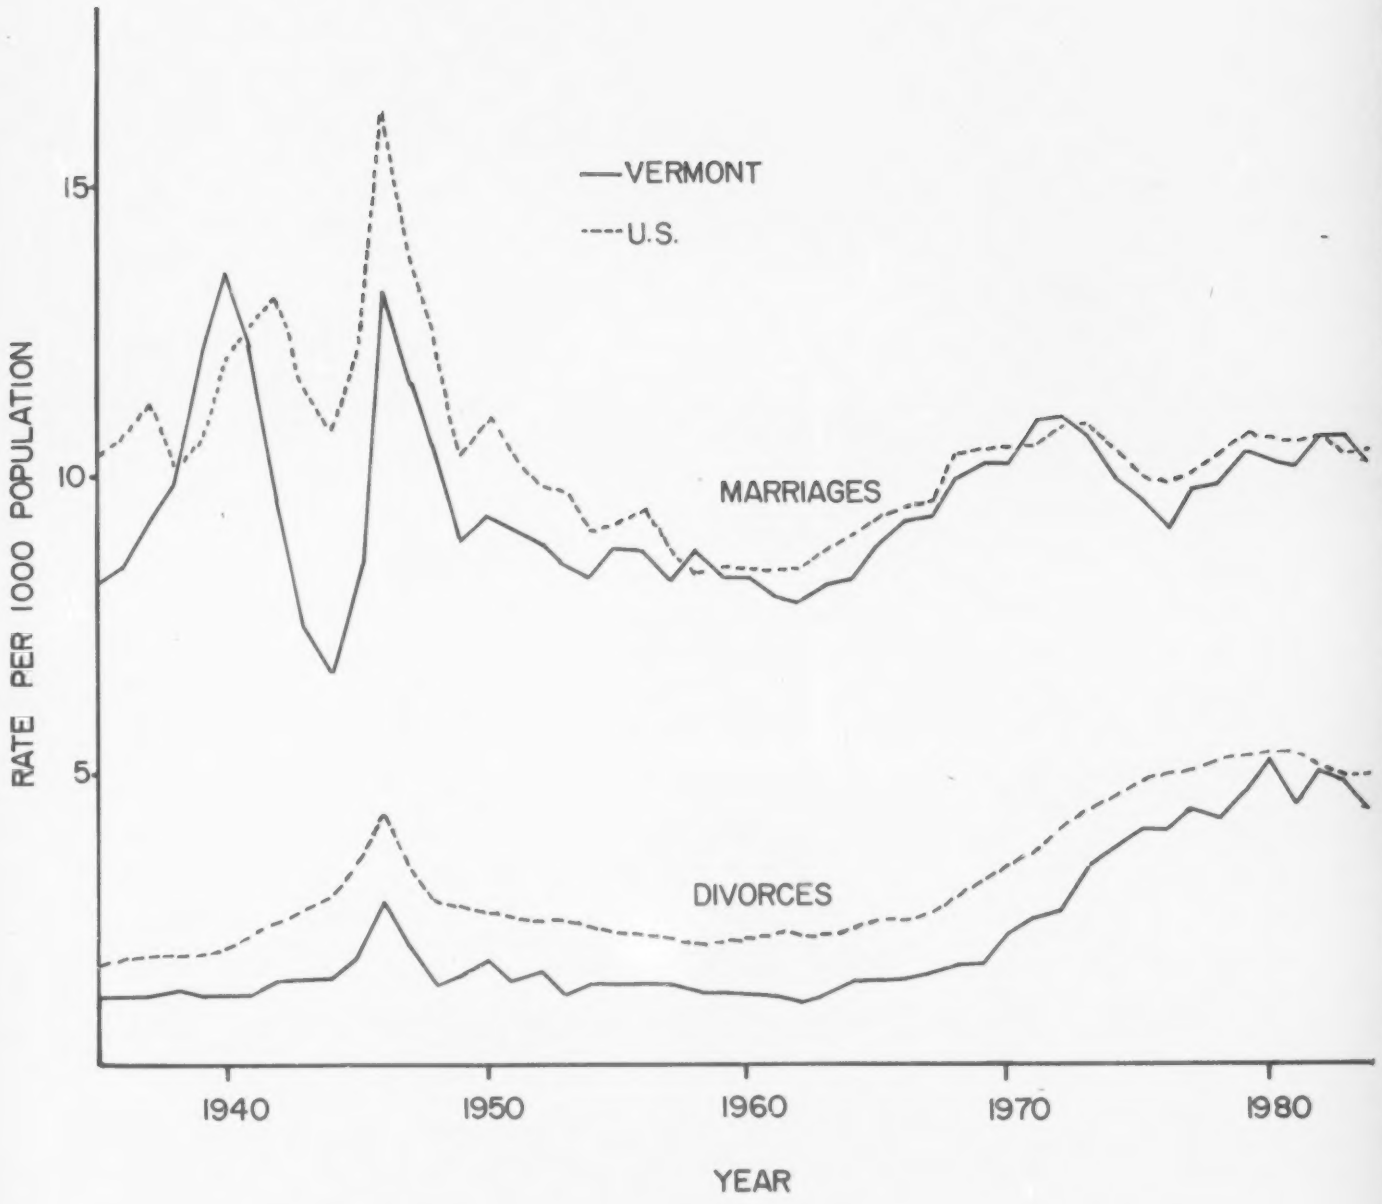
FETAL DEATHS - MARITAL STATUS OF MOTHER IS UNKNOWN.

MARRIAGE AND DIVORCE

Figure 11

MARRIAGE AND DIVORCE RATES
VERMONT AND U.S. 1935 - 1984



1983 U.S. DATA ARE PROVISIONAL

MARRIAGE AND DIVORCE

The 5,442 marriages occurring in Vermont in 1984 yield a rate of 10.3 marriages per 1,000 Vermonters, which is comparable to the United States 1984 provisional rate of 10.5.

Saturday was the most popular wedding day, with 72 percent of the marriages performed. Other days of interest include 7 weddings on New Year's, 26 on Valentine's Day, 4 on April Fool's Day, 13 on the Fourth of July, 5 on Halloween, 20 on Christmas Eve or Christmas, and 62 on either the groom's or bride's birthday.

In 1984, most wedding ceremonies (62 percent) were religious. However, most ceremonies which occurred Monday through Friday were civil (66 percent). Weekend weddings tended to be religious (69 percent). Weddings in which both the groom and the bride were marrying for the first time were predominantly religious (74 percent), while those in which both had been married previously were more often civil (57 percent).

In most of the marriages, the groom was older (69 percent), or the same age as (10 percent) the bride. The age at which people first marry has increased in the past 25 years. In 1959 the mean age of first time brides was 21.5 years and first time grooms was 23.5 years. In 1984 the ages were 23.6 and 25.6 years respectively. The number of remarriages has also increased. In 1959, sixteen percent of grooms and brides were remarrying. In 1984, 35 percent of grooms and 32 percent of brides were remarrying.

The 2,354 divorces granted in Vermont in 1984 represent 4.4 divorces for every 1,000 Vermonters. This is the second year of decline in the divorce rate, and the lowest rate since 1978. Nationally the 1984 divorce rate of 4.9 has also been declining from a record high of 5.3 in 1979 and 1981.

As in previous years, the plaintiff was usually the wife (65 percent), and the grounds for divorce were usually living apart for six months (99 percent).

The parents of 1.8 percent (2,588) of Vermont's children were divorced in 1984. The children come from 1,452 families.

Veteran's Administration Center	Windsor	White River Jct.
Vermont State Hospital	Washington	Waterbury
Central Vermont Medical Center	Washington	Berlin

APPENDIX B

SOURCES OF ERROR ON THE VERMONT BIRTH CERTIFICATE

In 1984 the Vermont Department of Health conducted a study to determine how accurately the data recorded on birth certificates reflect the actual pregnancy and birth events. Results showed that while the majority of data are accurate, some data items, specifically weeks of gestation, number of prenatal visits and month prenatal care began, should be used with caution. Detailed information about these items and their limitations is provided below. The Health Department and the hospitals have modified their data collection procedures as a result of the study in order to improve the quality of the data and, therefore, its usefulness.

WEEKS OF GESTATION

Vermont's birth certificate has two items which provide data for gestational age. Space is provided for the date the mother's last normal menses began, and for an estimate of weeks of gestation. Weeks of gestation can be calculated by subtracting the date of last menses from the date of birth. The space provided for weeks of gestation is intended as a physician's or midwife's estimate of gestational age based upon physical examination of the newborn. Prior to 1984, the data published had been the weeks given on the certificate if available. For those births where no gestational age given, the calculation was used.

The Health Department study revealed that the "weeks of gestation" item rarely reflected the physician's estimate. More often, it was a calculation based on dates, made either in the delivery room or by the medical records staff. Since the study, hospitals are reserving the weeks of gestation box for its intended purpose.

The weeks of gestation figures reported in this publication are computed from dates, if the dates are available and the computed weeks is between 28 and 44. The weeks reported on the certificate is only used if date data are unavailable (1,205 records). This should eliminate biases introduced by using the differing methods of reporting weeks, and by human error in the calculation of weeks.

NUMBER OF PRENATAL VISITS

Most Vermont obstetricians send copies of their expectant patients' charts to the intended hospital of delivery two or three weeks before the expected due date. This allows the prenatal chart to be at the hospital at the time of delivery.

Much of the medical data reported on the birth certificate comes from this prenatal chart. However, the hospital's copy of the prenatal record is not updated, and therefore any prenatal visits occurring after the chart has been sent to the hospital are not recorded on it.

The Health Department study showed that most Vermont hospitals added one visit per week to the recorded number of prenatal visits for every week between the time the chart was sent to the hospital and the actual birth. However, two hospitals, Rutland and Rockingham, recorded only those visits documented on the prenatal record. Therefore, care needs to be used in examining regional differences in number of prenatal visits, especially for residents of Rutland county.

Beginning in June, 1985, all hospitals are recording both the number of recorded prenatal visits, and the date of the last recorded visit. By 1986, this bias in the data will be eliminated.

MONTH PRENATAL CARE BEGAN

The birth certificate provides space for the month of pregnancy in which prenatal care began, with instructions to indicate first, second, third, etc. The Health Department study revealed that there were varying protocols used to determine when one month stopped and the next month began. As in the case of prenatal visits, apparent geographical differences in the month prenatal care began may be due to differing methods of reporting this data. Grouping the months, either into trimesters or into the categories 1-4 and 5+, will eliminate most of this bias.

Since June, 1985, all hospitals are reporting the actual date prenatal care began, and the month of pregnancy in which the care began is being calculated by computer.

APPENDIX C

DEFINITIONS OF THE 72 SELECTED CAUSES OF DEATH

Causes of Death	Category Numbers According to the International Classification of Diseases	
	Ninth Revision	Eighth Revision Adapted
Shigellosis and amebiasis	004, 006	004, 006
Certain other intestinal infections	007-009	008, 009
Tuberculosis	010-018	010-019
Tuberculosis of respiratory system	010-012	010-012
Other tuberculosis	013-018	013-019
Whooping Cough	033	033
Streptococcal sore throat, scarlatina and erysipelas	034-035	034
Meningococcal infection	036	036
Septicemia	038	038
Acute poliomyelitis	045	040-043
Measles	055	055
Viral hepatitis	070	070
Syphilis	090-097	090-097
All other infectious and parasitic diseases	001-003, 005, 020-032, 037, 039-041, 046-054, 056-066, 071-088, 098-139	Remainder of 000-136
Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues	140-208	140-209
...of lip, oral cavity, and pharynx	140-149	140-149
...of digestive organs and peritoneum	150-159	150-159
...of respiratory and intrathoracic organs	160-165	160-163
...of breast	174-175	174
...of genital organs	179-187	180-187
...of urinary organs	188-189	188, 189
...of all other and unspecified sites	170-173, 190-199	170-173, 190-199
Leukemia	204-208	204-207
Other malignant neoplasms of lymphatic and hematopoietic tissues	200-203	200-203, 208, 209
Benign neoplasms, carcinoma in situ, and neoplasms of uncertain behavior and of unspecified nature	210-239	210-239

NATURE OF INJURY CLASSIFICATIONS

Nature of Injury	Category According to the International Classification of Diseases 9th Revision
Fractures, dislocations, and sprains and strains of joints and adjacent muscles	800-848
Intracranial injury, excluding those with skull fracture	850-854
Internal injury of chest, abdomen and pelvis	860-869
Open wound and injury to blood vessels	870-904
Late effects of injuries, poisonings, toxic effects and other external causes	905-909
Superficial injury, contusion and crushing injury	910-929
Effects of foreign body entering through orifice	930-939
Burns	940-949
Injury to nerves and spinal cord	950-957
Certain traumatic complications and unspecified injury	958-959
Poisoning by drugs, medicaments and biological substances	960-979
Toxic effects of substances chiefly nonmedical as to source	980-989
Other and unspecified effects of external causes, complications of surgical and medical care not elsewhere classified	990-999

Steven G. Parren	Research and Statistics Analyst
Linda R. Peake	Computer Operator
Gail A. Rushford	Vital Statistics Field Specialist
Edna C. Webster	Vital Records Specialist

ERRATA:

SUMMARY STATISTICS: page 19

The four leading causes of death are heart disease with 318.1 deaths per 100,000 population, malignant neoplasms (cancer) with 197.9, cerebrovascular disease with 54.2 and accidents with 37.3. These rates are per 100,000 population, not the 1,000 stated.

BIRTHS: page 38

Selected characteristics by county of residence, table 7, is missing Windsor county, and state totals. A complete table is shown below.
